ElderCareAI Current Use Case Diagram

This diagram reflects the caregiver application and the separate administrator portal. The older adult is a managed profile, not an actor, because the current application provides no older-adult login or interface. Google Health supports onboarding and health-data synchronization.

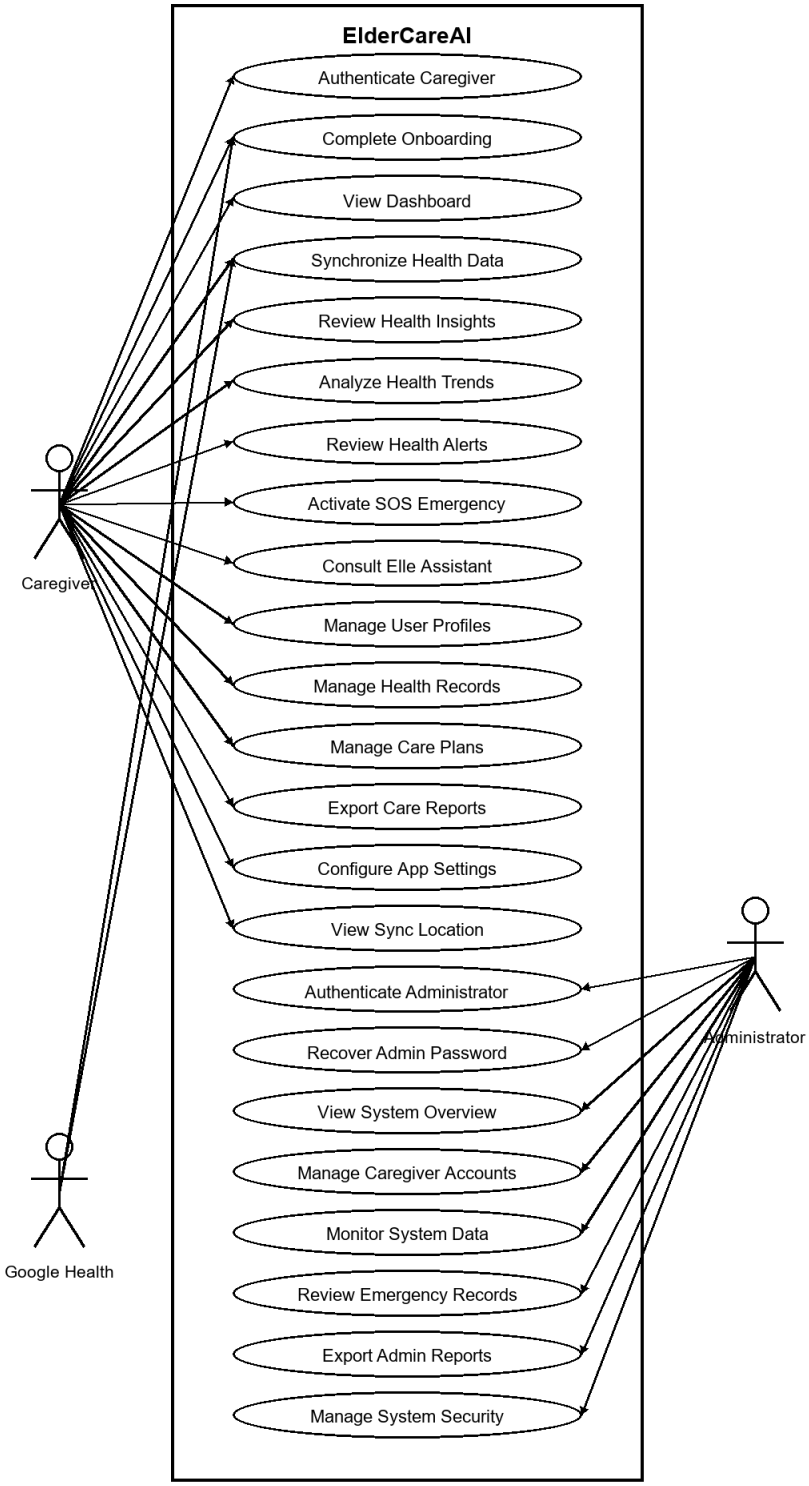

Figure 1. ElderCareAI current use case diagram

Current Application Flow

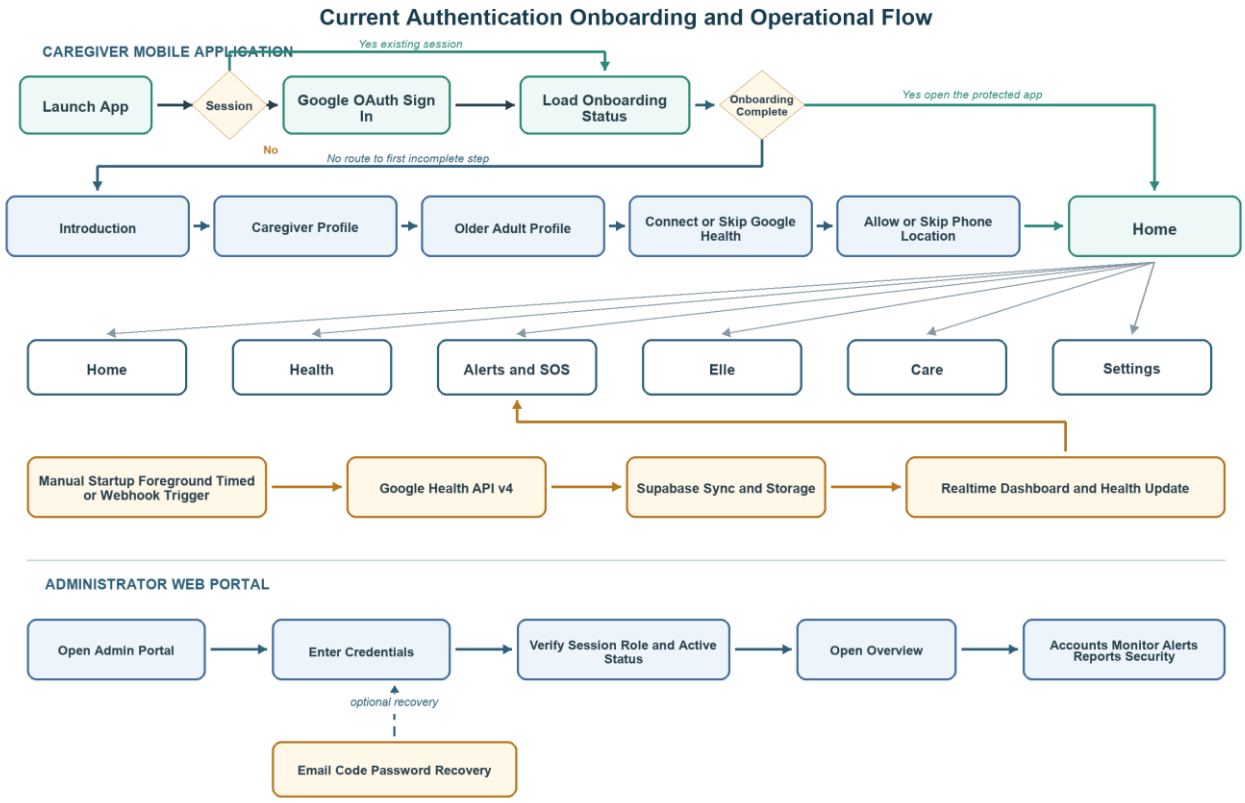

Figure 2. Authentication onboarding and operational flow

On launch, the app routes an authenticated caregiver to the first incomplete onboarding step or directly to Home. Onboarding proceeds through the introduction, caregiver profile, older-adult profile, optional Google Health connection, and optional foreground phone-location consent. After completion, the protected Home, Health, Alerts, Elle, Care, and Settings tabs become available.

Health data is reconciled from Google Health after manual, startup, foreground, timed active-app, or supported webhook triggers. Supabase stores the authorized records and sends database updates to the caregiver interface. The application does not directly pair with the tracker or continuously stream measurements from it.

Corrections to the Previous Diagram

- The older adult is represented as a managed profile rather than an application actor.
- Direct tracker pairing and Fetch Vitals are replaced by Google Health authorization and synchronization.
- Real-time location is replaced by the caregiver phone's last saved foreground synchronization location.
- Health predictions are non-diagnostic statistical trends and require sufficient synchronized history.
- Caregiver reports are generated as shareable PDFs, while administrator reports are exported as CSV files.
